Abstract Vocal learning is a rare skill in mammals, and we have limited information about the contexts in which they use it. Previous studies suggested that cetaceans in general are skilled at imitating sounds, but only few species have been studied to date. To expand this investigation to another species and to investigate the possible influence of the social environment on vocal learning, we studied the whistle repertoire of a female Risso's dolphin (*Grampus griseus*) that was stranded at an early age and was subsequently raised in a group of bottlenose dolphins (*Tursiops truncatus*). We show that this cross-fostered animal produced vocal signals more akin to those of its *Tursiops* poolmates than those of Risso's dolphins in the wild. This is one of very few systematic cross-fostering studies in cetaceans and the first to suggest vocal production learning in the Risso's dolphin. Our findings also suggest that social experience is a major factor in the development of the vocal repertoire in this species.

Introduction

Vocal production learning, the ability to modify the acoustic structure of vocalizations after hearing a model sound, is a significant step in the evolution of complexity in communication systems (Janik and Slater 2000). Humans make extensive use of vocal learning to develop speech, but this ability is rare in other animals. Indeed, while many birds are excellent vocal learners, non-human primates and many other mammals are not (Janik and Slater 1997). The only terrestrial, non-human mammals where we find strong evidence for this skill are bats (Knörnschild et al. 2010) and elephants (Poole et al. 2005; Stoeger et al. 2012). However, considerable evidence for vocal production learning can be found in marine mammals (Janik 2014). The best studied species here is the bottlenose dolphin (Richards et al. 1984), where each individual uses vocal learning to develop its own unique signature whistle (Janik and Sayigh 2013). These animals invent their own unique whistle modulation pattern seemingly by modifying whistles they heard early in life (Fripp et al. 2005). In baleen whales, vocal learning contributes to the development of song (Janik 2014), and pinnipeds have been found to copy sounds of other individuals (Reichmuth and Casey 2014). Despite abundant evidence for vocal learning in a few marine mammals, we still know little about vocal learning in the other species and its role in their social lives. To address these gaps, we investigated whether and how vocal learning can influence the vocal repertoire of a member of a species where learning has not been studied, a Risso's dolphin, that has been cross-fostered by a group of bottlenose dolphins. If vocal learning was important in social integration, we would expect the Risso's dolphin to deviate from its natural repertoire to match aspects of the bottlenose dolphin vocalizations and their use.

Methods

Animal history

In summer 2005, a mother–calf pair of Risso's dolphins was found in the harbour of Ancona (44° 62' N, 13° 50' E), Italy. The calf was a female, approximately 6 months of age. Both animals were transported to a local dolphin facility for veterinary treatments where they were kept in isolation. Nevertheless, the adult dolphin died after 2 days due to serious health complications. The orphaned calf was kept in quarantine for 30 days and subsequently moved to the Oltremare marine park in Riccione, Italy. In this new facility, the Risso's dolphin was initially kept with a group of 11 adult bottlenose dolphins (7 males, 4 females). Six of the males were moved to another facility in 2008. At the time of our study in 2011, the bottlenose dolphin group consisted of 1 male, 4 females, and a 1-year-old male calf. Three of these animals were caught in the Western Atlantic Ocean over 25 years ago and moved to Italy from Cuba and the USA. All others were born in captivity in Italy.

Data collection at Oltremare marine park

We conducted behavioural observations on close contact swimming (<1 m) of the Oltremare dolphins over several days from 30 November 2009 to 26 February 2010. This behaviour is an indicator of a close social relationship in dolphins (Connor et al. 2000). Dolphins were observed as one group (66 h) or in two groups separated by a gate (32 h with 2 males separated from the rest of the group). The Risso's dolphin was in the same pools as its preferred social partner, a female named Pelé, in all observation periods. In April 2011, we collected audio and video recordings during 30 different recording sessions over 14 consecutive days. We used an acoustic recording array consisting of four HTI-94-SSQ hydrophones (frequency response 2 Hz–30 kHz $\pm$ 1 dB). The hydrophone output signals were recorded with a TASCAM DR-680 digital recorder (sampling rate 96 kHz). During recording sessions, the Risso's dolphin and the bottlenose dolphins were free to swim in the main pool and all four holding pools of the facility. However, we analysed only segments when one animal was isolated from the group by choosing to swim alone in one of three holding pools that we fitted with individual hydrophones. This allowed us to match vocalizations to the emitter by using a time-of-arrival difference analysis of the acoustic signals to hydrophones (Janik et al. 2000). Over the period of recordings, the whistles of the Risso's dolphin were collected in 17 separate sessions, while each of the six poolmates was recorded for an average of 4 ± 2 (mean $\pm$ SD) different sessions.

Acoustic recordings of wild Risso's dolphins

Acoustic recordings in the Canary Islands were conducted continuously on a dispersed 4-hydrophone array, recording to a laptop with an Edirol FA-101 sound card. The acoustic array had 3 hydrophones tensioned to chains at 2 m of depth (2 HTI-96-MIN and one HTI-94-SSQ, frequency response 2 Hz–30 kHz $\pm$ 1 dB), and a fourth hydrophone at 10 m of depth (SRD hydrophone HS/150, frequency response 1–100 kHz $\pm$ 1 dB). Recordings were collected for as long as possible in a sea state of 3 or less (Beaufort scale) in dry weather using sampling rates of 96 kHz (33 % of recordings) and 192 kHz (67 % of recordings). Signal-to-noise ratio (SNR) was calculated for each of the 115 recorded whistles in a total recording time of 45 h in the presence of Risso's dolphins. Only 62 of these had a SNR of 6 dB or above which was our criterion for inclusion in the analysis.

Acoustic analysis

Audio segments containing whistles were visually selected by inspection of spectrograms (Hann window, FFT size 512, 100 % window width) using Adobe Audition 2.0. For each whistle, we extracted the pitch contour of the fundamental frequency using the beluga toolbox (available for download at: <http://biology.st-andrews.ac.uk/soundanalysis/>) for MATLAB®. From each whistle contour extracted with beluga, we measured the following 12 acoustic parameters using automatized procedures in MATLAB®: start frequency, end frequency, minimum frequency, maximum frequency, mean frequency, frequency range (maximum–minimum), duration, time to minimum frequency, time to maximum frequency, number of inflections in the contour (i.e. any change of slope from positive to negative or vice versa), number of steep sections in the contour (i.e. frequency change >500 Hz between one point and the following), and number of steps in the contour (i.e. steep sections preceded or followed by at least 25 ms of frequency modulation of less than 100 Hz).

Statistical analysis

After parameter standardization, we performed a principal component analysis (PCA) on all acoustic parameters using an orthogonal varimax rotation. The PCA reduced the original set of acoustic measurements to a new set of uncorrelated principal components (PCs). The scores of those PCs whose eigenvalues exceeded 1.0 were then used to calculate pairwise Euclidean distances for each whistle of the Risso's dolphin with those of the captive bottlenose dolphins and wild conspecifics. All analyses were performed in SPSS v. 20 (SPSS, Inc. 2010).

Results

Each of the bottlenose dolphins primarily used one individually distinctive and unique signature whistle when swimming alone [time analysed = 01 h 15 m 59 s; $N_{\text{whistles}} = 151$ (8–40 per animal)] (Fig. 1a). The cross-fostered Risso's dolphin also produced only one unique whistle type (Fig. 1b) when swimming in isolation (time analysed = 02 h 54 m 24 s; $N_{\text{whistles}} = 192$), similar to the use of signature whistles found in bottlenose dolphins. Descriptive statistics of the whistle parameters for this type are presented in Table 1a. Interestingly, recurring whistle contours in our sample of wild Risso's dolphin whistles were rare (Fig. 1c) (time analysed = 45 h; $N_{\text{whistles}} = 62$).

The PCA reduced the 12 acoustic parameters measured from the fundamental frequency to four independent PCs. These four components explained 81.93 % of the total variance (PC1 = 24.56 %, PC2 = 22.88 %, PC3 = 19.82 %, PC4 = 14.68 %). Table 2 shows the factor

loadings for each principal component. In particular, the main separating PC (PC1) represented primarily maximum frequency, mean frequency, frequency range, duration, and time to maximum frequency. In the space defined by the PCs, the signature whistles of the Risso's dolphin made a distinctive cluster within the range of variation of bottlenose dolphin vocalizations, and they were separated from the cluster made by whistles from wild conspecifics recorded in the Canary Archipelago (Fig. 2). Mean Euclidean distances indicated that similarity was higher between the whistles of the captive Risso's dolphin and those of the bottlenose dolphins (2.87 ± 0.004 ; mean $\pm$ SE pairwise distances) than between the whistles of the captive and the wild Risso's dolphins (3.074 ± 0.009). Interestingly, the whistle parameters of the Risso's dolphin whistle most closely matched those of an adult female (Pelé) that she spent most of her contact time with (time spent at more than 1 m from conspecifics: 74 %, time close to Pelé only: 15 %, time close to other dolphins: 11 %) and those of the

Discussion

The evidence presented here suggests that Risso's dolphins are capable of vocal learning. We analysed the whistle repertoire of a female that became orphaned at an early age and grew up in a community of captive bottlenose dolphins. We found that the cross-fostered Risso's dolphin produced almost exclusively one whistle type when in isolation, similar to the use of signature whistles found in bottlenose dolphins (Janik and Sayigh 2013). Interestingly, recurring whistle contours in our sample of wild Risso's dolphin whistles were rare. Together with the very low whistle rate we found for wild Risso's dolphins in the Canary Islands, this may indicate an absence of signature whistles in wild Risso's dolphins. However, Risso's dolphin behaviour in the Canaries may differ from that in other geographic locations. A signature whistle has been found in one other captive Risso's dolphin, but this animal was also housed with bottlenose dolphins (Caldwell et al. 1969). Killer whales have also been found to change their vocal behaviour when housed with bottlenose dolphins (Musser et al. 2014), further supporting the importance of the social environment for repertoire development in delphinids. It remains to be seen whether Risso's dolphins use signature whistles when with conspecifics.

Overall, our results show that the whistles of the cross-fostered Risso's dolphin were much closer to those of its bottlenose dolphin pool mates than to wild Risso's dolphins from the Canary Islands (Fig. 2). This was also confirmed

by the analysis of Euclidean distances, chosen as a similarity measure. While the Canary Island population may differ from Risso's dolphins in the Adriatic Sea, a comparison of our data with published data from wild Risso's dolphin from the Azores and from Scotland (Rendell et al. 1999) also suggests that the cross-fostered individual used its pool mates as a model for its whistle. Table 1b shows that average values for start, end, minimum, maximum, and mean frequency of the captive Risso's dolphin whistles were considerably closer to the average bottlenose dolphin whistles from its pool than to those from these other conspecific populations. Little is known about wild Risso's dolphin vocalizations, and their social organization appears to be different from that of well-known vocal learners like bottlenose dolphins or killer whales (*Orcinus orca*) (Hartmann et al. 2008). Risso's dolphins live in relatively stable, non-matrilineal groups. Thus, it is difficult to speculate how Risso's dolphins would use vocal learning in the wild.

In conclusion, our results provide evidence that the cross-fostered Risso's dolphin developed a signature whistle and used overall whistle parameters that were more similar to bottlenose dolphins than to those used by wild Risso's dolphins. Cross-fostering is one of the few strong approaches to the study of vocal learning and as shown here can add information on the role of social partners in its usage. Our study only describes one animal and can therefore only suggest the influence of vocal learning on whistle development. Changes in vocalizations could be achieved through copying as in vocal production learning, or through selection of pre-existing vocalization patterns as would be the case in contextual learning. The large differences in parameters, especially in start frequency and frequency range, between the cross-fostered animal and the three wild populations of Risso's dolphins suggest that this

Fig. 2 Whistles plotted in the space defined by principal components. The signature whistles of the captive Risso's dolphin made a distinctive cluster within the range of variation of bottlenose dolphin

vocalizations, which was separated from the cluster made by whistles from wild conspecifics

is a case of vocal production learning rather than using already existing whistles from a pre-existing repertoire. However, future studies need to address the role of signature vocalizations in this species as well as the mechanism of learning with a larger sample size.

Acknowledgments We would like to thank the marine mammal staff of the Oltremare Marine Park, especially Daniele Zanzi and Barbara Biancani. We are also grateful to Giulia Bemporad for help with data collection, Thomas Götz and Volker Deecke for providing helpful comments and Olivier Pierre Friard for technical support.
